## **Session 6 09/22**

<ol> <li>Give the definition of a tertiary structure.</li> <li>Interactions between R groups on the SAME polypeptide.</li> </ol>
<ul> <li>2. What bonds are present in a tertiary structure?</li> <li>Covalent, ionic, van der walls, hydrogen + all other types of interactions/bonding.</li> <li>Reminder: salt bridge = ionic bond</li> </ul>
<ul><li>3. What is the difference between cysteine and cystine?</li><li>Cysteine = the amino acid</li><li>Cystine = Disulfide bridge</li></ul>
<ul><li>4. Give the definition of a quaternary structure.</li><li>- When two or more polypeptides (subunits) interact. All groups are allowed to interact here.</li></ul>
<ul><li>5. What bonds are present in a quaternary structure?</li><li>- All 5 interaction/bonds are able to be present. However, covalent bonds are rare.</li></ul>

- 6. Which structure requires specific ions to function?
- Quaternary structure
- 7. Define the following:
  - Dimer
    - -Two subunits/two polypeptides
  - Homodimer
    - -Two of the same subunits
  - Heterodimer
    - -Two different subunits
  - Heterotetramer
    - -Four different subunits
- 8. What are used to distinguish subunits?
- -Greek letters
- 9. What is the most general function of a protein?
- -All proteins bind to some sort of molecule.

We know that proteins bind and have binding site. The proteins shape is dependent on the R groups! They create the specificity for the binding protein.
